Abstract
Diabetes mellitus is the most common serious metabolic disorder and it is considered to be one of the five leading causes of death in the world. Hyperglycemia-mediated oxidative stress plays a crucial role in diabetic complications. Hence, this study was undertaken to evaluate the protective effect of hesperetin on the plasma glucose levels and on the antioxidant defense system in streptozotocin-induced diabetic rats. Oxidative stress was assessed by the reduction in the enzymic antioxidant enzymes like superoxide dismutase (SOD), catalase (CAT), glutathione peroxidase (GPx) and nonenzymic antioxidant Vitamin C, E and reduced glutathione (GSH) were observed in the liver and kidney tissues of diabetic control rats as compared to control rats. Oral supplementation of hesperetin to diabetic rats for 45 days significantly brought back the enzymic and nonenzymic antioxidants to normalcy. These findings suggest that hesperetin (40mg/kg bw) exerts a protective effect in diabetes by attenuating hyperglycemia-mediated oxidative stress and antioxidant competence in hepatic and renal tissues.

Key words: Hesperetin, enzymic and nonenzymic antioxidants, plasma glucose.

INTRODUCTION
Chronic hyperglycemia a clinical hallmark to diabetes results in metabolic imbalances and pathological changes in many cases [1]. Oxidative stress plays an important role in the etiology of diabetes and its complications. Decreased concentration of antioxidant enzymes and increased level of peroxidation products and reactive oxygen species were detected in type 2 diabetes [2].

Free radicals have significant role in the causation of several diseases like diabetes. Disease [3, 4]. Diabetes as an oxidant milieu evokes free radical generation via [5, 6, 7, 8] a) Non-enzymatic glycosylation of protein (apolipoproteins, enzyme and receptors) leads to chronically elevated lipids and lipoprotein b) Increased glucose metabolism through aldose reductase pathways altering the intracellular redox balance. Increased de novo synthesis of diacylglycerol and subsequent attenuation of antioxidant defense system creating oxidative stress.
These effects resulted in increased levels of lipids and lipoproteins to free radical generation. Increased production of reactive O2 species and N2 species (ROS/RNS) in human with diabetes contribute to endothelial, vascular and neurovascular dysfunction [9] and the changes in structural and functional integrity of subcellular organelles and membrane [10]. Oxidative stress causes damage to DNA, Lipids, Proteins, disruption in cellular homeostasis and accumulation of damaged metabolites results [10]. The defence system established to diminish the damaging effect of free radical species includes enzymes such as Catalase, Glutathione peroxidase, Superoxide dismutase and non enzymatic constituents and vitamins. Recent reports state that dietary supplementation with natural antioxidants such as vitamin C and E, melatonin, flavanoids and amino acid L-arginine diminish the oxidative stress in diabetic state [11, 12, and 13] and improves endothelial cell function [14].

Flavanoids are non-nutritive dietary components that are widely distributed in plants, several types of vegetables and fruits, and it has been suggested that flavanoids are associated with potential health benefits [15, 16]. The flavanoid hesperitin is the aglycone of hesperidin found in sweet oranges, other citrus fruits and some herbs. Biological activities of hesperitin include antioxidant, bone-sparing and lipid lowering effects. Hesperitin also plays a significant role in inflammation and cancer inhibition.

MATERIALS AND METHODS
Animal Management
Nine-week-old adult male albino rats of Wistar albino strain, weighing 120-150 g were acclimatized for one week at air conditioned room (25± 1°C) and relative humidity (55%) in a 12-hour light/dark cycle in a room under hygienic condition. This study was carried out in the animal house of Srimad Andavan College, Tiruchirapalli and was approved by the Institutional Ethical Committee (SAC/IAEC/BC/2015/Ph.D-009). Animals were fed with pelleted rat chow and water ad libitum.

Source of Chemicals
The synthetic compound and all the chemicals and solvents were of analytical grade and purchased from Sigma-Aldrich Co and Himedia Laboratories Pvt.Ltd., Mumbai.

Induction of diabetes
The rats were rendered diabetes by a single intraperitoneal injection of STZ (45mg/kg body weight) in a freshly prepared citrate buffer (0.1M, pH 4.5) after an overnight fast. STZ injected rats were given 20% glucose solution for 24hr to prevent initial drug-induced hypoglycemic mortality. After 72hrs of STZ injection rats exhibited massive glycosuria and hyperglycemia was confirmed by measuring the fasting blood glucose concentration. The rats with blood glucose levels more than 235mg/dL were considered diabetic and used for the experiment.

Treatment group protocol
The animals were divided into six groups, each comprised of nine rats.
Group I – Normal Rats
Group II – Rats were induced with intraperitoneal injection of STZ (45mg/kg body weight) and treated with Hesperetin (20mg/kg body weight in saline).
Group III – Rats were induced with intraperitoneal injection of STZ (45mg/kg body weight) and treated with Hesperetin (40mg/kg body weight in saline).
Group IV - Rats were induced with intraperitoneal injection of STZ (45mg/kg) and treated with Glibenclamide (1mg/kg body weight in saline).
Group V – Rats were treated with Hesperetin (40mg/kg body weight in saline).
Group VI - Rats were induced with intraperitoneal injection of STZ (45mg/kg) and treated with Glibenclamide (1mg/kg body weight in saline). Collection of blood sample
At the end of the experimental period, the rats were sacrificed. Plasma and serum were separated Treatment continued for 45 consecutive days. Before the treatment (0th, 3rd, 15th, 30th day and the end 45days plasma levels were estimated using the glucose oxidase method. At the
end of the experimental period, the rats were sacrificed. Plasma and serum were separated from
blood by centrifuging the samples at 5000 rpm for 10 min and stored in a refrigerator until
analysed.

Statistical analysis
Results are presented as mean ± S.D for six rats in each group. Data were analyzed by one-way
analysis of variance (ANOVA) followed by Duncan's Multiple Range Test (DMRT) using SPSS
version 10 (SPSS, Chicago, IL, USA). The limit of statistical significance was set at \( p < 0.05 \).

RESULTS
Table 1 shows a significant \( (p<0.05) \) increase in the level of blood glucose. Oral administration
of hesperetin to diabetic rats significantly \( (p<0.05) \) decreased the levels of blood glucose.

Values are given as means ± S.D from six rats in each group. Values In each column, different
superscript letters mean significant differences at \( p < 0.05 \) (DMRT).

Table 2 represents significant \( (p<0.05) \) decrease in catalase, SOD and GP\(_x\) activities in the liver
and kidney of diabetic rats compared with normal rats. Diabetic rats with hesperetin treatment
showed significant \( (p<0.05) \) increase in CAT, SOD and GP\(_x\) activities which reflect restoration of
the antioxidant enzyme systems to near normal values.

Table 3 represents the levels of Vitamin C, Vitamin E and reduced glutathione in the liver and
kidney tissues of diabetic control rats. Diabetic rats exhibited a significant \( (p<0.05) \) fall in the
levels of low molecular weight antioxidants when compared to normal control. Oral
administration of hesperetin to diabetic rats shows improvement in the antioxidant level.

DISCUSSION
Diabetes mellitus is due to abnormality of carbohydrate metabolism and it is mainly linked with less insulin level or insensitivity of target organs to insulin [17]. The oral administration of hesperetin to diabetic rats reduced the plasma glucose levels to near normal glycemic concentration and is an essential trigger for the liver to revert its normal homeostasis during diabetes. SOD is an enzymatic antioxidant which catalyzes the conversion of superoxide radical to hydrogen peroxide and molecular oxygen. Other enzymic antioxidant CAT catalyzes the reduction of hydrogen peroxides and protects the tissues against reactive hydroxyl radicals. In the present study, the low levels in the activity of SOD, CAT and GPX in diabetic rats indicated diabetes-induced stress and a significant elevation of these antioxidant enzymes activities was observed in the hesperetin treated diabetic rats which might be due to its scavenging property.

Vitamins C and E are diet derived and detoxify free radicals directly. [18] Reported that Vitamin C depletion leads to formation of hydroperoxides and this may due to increased utilization in trapping the oxyradicals. Vitamin E a lipophilic antioxidant transfers its phenolic hydrogen to a peroxyl free radical of peroxidized polyunsaturated fatty acids, thereby breaking the radical chain reaction and preventing the peroxidation of membrane lipids [19]. The administration of hesperetin to diabetic group of rats significantly reverted back the altered back the altered levels to near normalcy, which in turn reveals the antioxidant potential of hesperetin. GSH functions as free radical scavenger and in the repair of free radical caused biological damage [20].
